MPQ7220

6-Channel, Max 100mA/Ch Boost LED Driver, AEC-Q100 Qualified

DESCRIPTION

The MPQ7220 is a boost converter with six channel current sources. It is designed for driving automotive tail lights.

The MPQ7220 uses peak current mode as its PWM control architecture. The switching frequency can be programmed by a resistor. It independently regulates the current in each LED string to the value set by an external current-setting resistor.

The device applies six internal current sources, one in each LED string terminal to achieve a current balance with 2.5% current regulation accuracy between strings. The low headroom voltage for LED regulation and on resistance of switching MOSFETs allows for high efficiency.

The MPQ7220 has rich protection modes to guarantee safe operation. Protection modes include OCP (over-current protection), OVP (over-voltage protection), OTP (over-temperature protection), and LED string short and open protection. The LED current decreases at high temperatures.

The MPQ7220 is available in QFN-24 (4mmx4mm) and TSSOP28-EP packages.

FEATURES

- 3.5V to 36V Input Voltage Range
- Six Channels with Max 100mA per Channel
- Internal 100mΩ, 50V MOSFET
- Programmable Up to 2.2MHz f_{SW}
- External Sync SW Function
- PWM Dimming (Dimming Frequency from 100Hz to 20kHz)
- Excellent EMI Performance, Spread Spectrum
- Disconnect V_{OUT} from V_{IN}
- 2.5% Current Matching
- Cycle-by-Cycle Current Limiting
- Programmable LED Short Threshold
- Programmable OVP Threshold
- LED Current Auto-Decrement at High Temperatures
- LED Short/Open, OTP, OCP, Inductor Short Protection
- Fault Indicator Signal Output
- Available in QFN-24 (4mmx4mm) and TSSOP28-EP Packages
- AEC-Q100 Grade 1

APPLICATIONS

- Automotive Tail Lights

PIN FUNCTIONS

QFN24 Pin #	TSSOP28-EP Pin #	Name	Description
1	5	DIM	**DIM signal input.** Apply a PWM signal on DIM for brightness control. Pulled low internally. A 100Hz to 20kHz PWM signal is recommended. Pull this pin high if the dimming function not used.
2	2, 4, 6, 22, 24	NC	**Not connected.**
3	7	FREQ/SYNC	**Switching frequency setting and SYNC pin.** Connect a resistor between this pin and GND to set the converter's switching frequency. Or connect an external clock to sync the boost switching frequency.
4	8	EN	**IC enable pin.** Pull this pin to high enable the IC. Pull this pin low to force the IC to enter shutdown mode.
7	11	COMP	**Compensation pin**.
8	12	FF	**Fault flag pin.** Open drain during normal operation, pulled low in any fault mode. Float FF if not used.
9	13	ISET	**LED current setting.** Tie a current-setting resistor from this pin to ground to program the current in each LED string.
5, 6, 10	9, 10, 14	AGND	**Analog ground.**
11	15	LED6	**LED string 6 current input.** Connect the LED string 6 cathode to this pin.
12	16	LED5	**LED string 5 current input.** Connect the LED string 5 cathode to this pin.
13	17	LED4	**LED string 4 current input.** Connect the LED string 4 cathode to this pin.
14	18	LED3	**LED string 3 current input.** Connect the LED string 3 cathode to this pin.
15	19	LED2	**LED string 2 current input.** Connect the LED string 2 cathode to this pin.

PIN FUNCTIONS *(continued)*

QFN24 Pin #	TSSOP28-EP Pin #	Name	Description
16	20	LED1	**LED string 1 current input.** Connect the LED string 1 cathode to this pin.
17	21	PGND	**Step-up converter power ground.**
18	23	SW	**Drain for the internal low-side MOSFET switch.** Connect the power inductor to SW.
19	25	OVP	**Over-voltage protection pin.** Use a voltage divider to program the OVP threshold (see the Application Information section on page 20). Do not float this pin.
20	26	STH	**Short LED protection threshold set pin.** An 18µA current source flows out of this pin. Connect a resistor from STH to GND to set the protection threshold. The short protection threshold is 5V if this pin is floated.
21	27	FSP	**Switching frequency spread spectrum pin.** An 18µA current source flows out of this pin. Connect a resistor from FSP to GND to set the voltage. If FSP < 0.4V, the jitter frequency is 1/20 of the central frequency. If FSP = 0.45V to 1.4V, the jitter frequency is 1/32 of the central frequency. If FSP > 1.4V or is floated, the frequency spread spectrum is disabled.
22	28	VCC	**5V LDO output pin.** VCC provides power for the internal logic and gate driver. Place a ceramic capacitor as close as possible to this pin to reduce noise.
23	1	SD	**External disconnect PMOS gate drive pin.** Turn off the external PMOS in a fault condition. Float this pin if not used.
24	3	VIN	**Power supply input.** VIN supplies the power to the IC.
Exposed pad	Exposed pad	Exposed pad	**Exposed pad.** It has no internal electrical connection to AGND and PGND. Connect exposed pad to external GND plane on board for optimal thermal performance.

EVQ7220-F-00A [5] …….......……44 ……..7.…°C/W

Notes:
1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA}, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX) - T_A) / θ_{JA}. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) Operation devices at junction temperature up to 150°C is possible; contact MPS for details.
4) Measured on JESD51-7, 4-layer PCB.
5) Measured on MPS standard EVB of MPQ7220, 2-layer, 1oz. PCB.

ELECTRICAL CHARACTERISTICS

V_{IN} = 12V, V_{EN} = 2V, T_J = -40°C to +125°C, typical values at T_J = 25°C, unless otherwise noted.

Parameter	Symbol	Condition	Min	Typ	Max	Units

# FUNCTIONAL BLOCK DIAGRAM

Figure 1: Functional Block Diagram

OPERATION

The MPQ7220 employs a programmable, constant-frequency, peak current mode, step-up converter with up to six channels of regulated current sources to drive the array of white LEDs.

Internal 5V Regulator

The MPQ7220 includes an internal linear regulator (VCC). When V_{IN} exceeds 6V, this regulator outputs a 5V power supply to the internal MOSFET switch gate driver and the internal control circuitry. The VCC voltage drops to 0V when the chip shuts down. The chip remains disabled until VCC exceeds the UVLO threshold.

System Start-Up

When V_{IN}, EN, and DIM are enabled, the MPQ7220 checks the topology connection. First, the IC draws current from the SD pin to enable the input disconnect PMOS turn-on (If this MOS is used). After a 500µs delay, the IC monitors the OVP pin to see whether the output is shorted to GND or not. If the OVP voltage is less than 100mV, the IC is disabled and latches off. After that, the MPQ7220 continues to check other safety limits, such as LED open and over-voltage protection. If all the protection tests pass, the IC then starts boosting the step-up converter with an internal soft start.

The recommended power-on sequence is the following: $V_{IN} \rightarrow$ EN $\rightarrow$ PWM dimming signal.

Step-Up Converter

The MPQ7220 employs peak current mode control to regulate the output energy. At the beginning of each switching cycle, the internal clock turns on the internal N-MOSFET (in normal operation, the minimum on time is about 100ns). A stabilizing ramp added to the output of the current-sense amplifier prevents sub-harmonic oscillations for duty cycles greater than 50%. This result is fed into the PWM comparator. When the summed voltage reaches the output voltage of the error amplifier, the internal MOSFET turns off.

The output voltage of the internal error amplifier is an amplified signal of the difference between the reference voltage and the feedback voltage. The converter automatically chooses the lowest

active LEDx pin voltage to provide a high enough output voltage to power all the LED arrays.

If the feedback voltage drops below the reference, the output of the error amplifier increases. This results in more current flowing through the MOSFET, thus increasing the power delivered to the output. This forms a closed loop that regulates the output voltage.

Under light-load conditions, especially in the case of $V_{OUT} \approx V_{IN}$, the converter runs in pulse-skipping mode where the MOSFET turns on for a minimum on time, and then the converter discharges the power to the output for the remaining period. The external MOSFET remains off until the output voltage needs to be boosted again.

LED Current Setting

The LED current amplitude is set by an external resistor from ISET to GND. The LED current amplitude setting follows Equation (1):

$$I_{LED}(mA) = \frac{1245}{R_{ISET}(k\Omega)} \qquad (1)$$

For R_{ISET} = 12.4kΩ, the LED current is 100mA.

PWM Dimming Control

By applying a PWM signal to the DIM pin, the amplitude of the LED current remains at I_{SET}. The LED current is chopped by the input PWM signal, applying an external 100Hz to 20kHz PWM waveform to DIM for PWM dimming. During PWM dimming, the part stops switching when DIM is below 0.4V and the LED current is zero. The part resumes normal operation with a nominal LED current when DIM exceeds 1.2V.

Unused LED Channel Setting

The MPQ7220 automatically detects the unused LED string and removes it from the control loop during start-up by connecting the LEDx pin of an unused channel to GND. If employing 5 strings, connect the LED6 to GND. If using 4 strings, connect the LED5 and LED6 to GND, and so on.

Frequency Spread Spectrum

The MPQ7220 uses switching frequency jitter to spread the switching frequency spectrum. It

reduces the spectrum spike around the switching frequency and its harmonic frequencies.

The FSP pin can program the dithering range, and the modulation frequency is fixed to 1/150 of the switching frequency. FSP is a current-source output (18µA). Connect a resistor to program its voltage.

If FSP < 0.4V, the jitter frequency is 1/20 of the central frequency.

If FSP = 0.45V to 1.4V, the jitter frequency is 1/32 of the central frequency.

If FSP > 1.4V or is left floating, the frequency spread spectrum is disabled.

Programming and Synchronizing the Switching Frequency

The switching frequency is programmed through an external resistor or an external clock on the FREQ/SYNC pin. The switching frequency can be determined with Equation (2):

$$F_{SW}(kHz) = \frac{22000}{R_{FRE}(k\Omega)} \qquad (2)$$

For R_{OSC} = 46.4kΩ, the switching frequency is set to 470kHz.

Synchronize the switching frequency using an external clock to improve EMI, efficiency, and thermal performance.

Protection

The MPQ7220 includes open string protection, short string protection, short LEDx to GND protection, over-current protection, short out to GND protection, and thermal protection. Once the protection is triggered, the fault flag (FF) pin pulls to GND. FF is released to high with a 750µs delay after the IC recovers from protection.

Open String Protection

Open string protection is achieved through detecting the voltage of the OVP pin and the LED1-6 pins. During operation, if one string is open, the respective LEDx pin voltage is pulled low to ground. The IC keeps charging the output voltage until it reaches the over-voltage protection (OVP) threshold. If the OVP point has been triggered, the chip stops switching and marks off the fault string that has an LEDx

pin voltage below 100mV. Once marked, the remaining LED strings force the output voltage back into normal regulation. The string with the largest voltage drop determines the output regulation value. The marked-off string sends a 10µs pulse current to check whether an open fault is removed after every 500µs delay, so open string protection is recoverable.

Short String Protection

The MPQ7220 monitors the LEDx pin voltages to determine whether a short string fault has occurred. If one or more strings are shorted, the respective LEDx pins tolerate high voltage stress. If an LEDx pin voltage exceeds the protection threshold, an internal counter is started. If this fault condition lasts for 7.7ms, the fault string is marked off and disabled. Once a string is marked off, it disconnects from the output voltage loop until the short is removed.

The short protection threshold is set by the external STH pin. An 18µA current flows out of the pin. Connect a resistor from STH to AGND to get a voltage (V_{STH}). The threshold is 10 times V_{STH} when V_{STH} < 1.4V. When STH is floating or V_{STH} > 1.4V, the short protection threshold is set to 5V.

When all LEDx voltages exceed the threshold for 480ms, all strings are marked off. The IC is on standby until the strings release from shorting.

Short LEDx to GND Protection

When LEDx shorts to GND, the COMP voltage increases and saturates. When the COMP saturated time lasts for 20ms, protection is triggered, the FF pin pulls low, and the SD pin is pulled high to turn off the external P-MOSFET. The IC also latches off.

Short V$_{OUT}$ to GND Protection

When V_{OUT} shorts to GND, the OVP voltage decreases and kicks the low threshold for 10µs. Then the protection is triggered. The SD pin is pulled high to turn off the external P-MOSFET, and V_{OUT} is disconnected from V_{IN}.

Cycle-by-Cycle Current Limit

To prevent the external components from exceeding the current stress rating, the IC has cycle-by-cycle current limit protection. When the

current exceeds the current limit value, the IC stops switching until the next clock cycle.

Latch-Off Current Limit Protection

Extreme conditions like excess current or an inductor short may cause device damage. Therefore, the MPQ7220 provides a latch-off current limit protection when the current flowing through an internal MOSFET reaches the threshold (8A) and lasts for five switching cycles.

Thermal Protection

To prevent the IC from damage when operating at exceedingly high temperatures, thermal protection is implemented in this chip by detecting the silicon die temperature.

Over-Temperature LED Current Decrement

When the die temperature exceeds 140°C, the MPQ7220 automatically decreases the LED current amplitude.
Figure 2: I_{LED} Decreases with Temperature

Thermal Shutdown

When the die temperature exceeds the upper threshold (T_{ST}), the IC shuts down. It recovers to normal operation when the die temperature drops below the lower threshold. The hysteresis value is typically 20°C.

APPLICATION INFORMATION

LED Current Setting

The LED current amplitude is set by an external resistor connected from ISET to GND. The LED current amplitude setting is determined with Equation (3):

$$I_{LED}(mA) = \frac{1245}{R_{ISET}(k\Omega)} \qquad (3)$$

For R_{ISET} = 12.4kΩ, the LED current is 100mA.

Setting the Over-Voltage Protection (OVP)

The voltage divider sets the over-voltage protection (OVP) point (see Figure 3). Calculate V_{OVP} with Equation (4):

$$V_{OVP}(V) = 2V \times \frac{R_3 + R_4}{R_4} \qquad (4)$$

Normally, the OVP point is set about 10% to 30% higher than the LED voltage.

Switching Frequency

The frequency can be programed by an external resistor or an external clock on the FREQ/SYNC pin. Calculate the switching frequency using Equation (5):

$$f_{SW}(kHz) = \frac{22000}{R_{FRE}(k\Omega)} \qquad (5)$$

For R_{FRE} = 46.4kΩ, the switching frequency is set to 470kHz.

Synchronize the switching frequency using an external clock to improve EMI, efficiency, and thermal performance.

Selecting the Input Capacitor

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input capacitor impedance at the switching frequency should be less than the input source impedance to prevent the high-frequency switching current from passing through to the input. Use ceramic capacitors with X5R or X7R dielectrics for their low ESR and small temperature coefficients.

For most applications, a 10µF ceramic capacitor is sufficient.

Selecting the Inductor

The MPQ7220 requires an inductor to supply a higher output voltage while being driven by the input voltage. A larger-value inductor results in less ripple current, lower peak inductor current, and less stress on the internal N-channel MOSFET. However, the larger-value inductor has a larger physical size, higher series resistance, and lower saturation current.

Choose an inductor that does not saturate under worst-case load conditions. Select the minimum inductor value to ensure that the boost converter works in continuous conduction mode with high efficiency and good EMI performance.

Calculate the required inductance value using Equation (6) and Equation (7):

$$L \geq \frac{\eta \times V_{OUT} \times D \times (1-D)^2}{2 \times f_{SW} \times I_{LOAD}} \qquad (6)$$

$$D = 1 - \frac{V_{IN}}{V_{OUT}} \qquad (7)$$

Where V_{IN} and V_{OUT} are the input and output voltages, respectively. f_{SW} is the switching frequency, I_{LOAD} is the LED load current, and η is the efficiency.

With the given inductor value, the inductor DC current rating is at least 40% greater than the maximum input peak inductor current for most applications. The inductor's DC resistance should be as small as possible for higher efficiency.

Selecting the Output Capacitor

The output capacitor keeps the output voltage ripple small and ensures feedback loop stability. The output capacitor impedance must be low at the switching frequency. Ceramic capacitors with X7R dielectrics are recommended for their low ESR characteristics. For most applications, a 10µF ceramic capacitor is sufficient.
